US 8,437,883 B2

| 3 | 4 |

another smart meter that was previously selected to be monitored. The voltage controller may be configured to create a connection to said smart meter and terminate a connection to said another smart meter. The sua sponte smart meter data received from said smart meter may be representative of a low voltage limiting level in the system. The voltage controller may be configured to: store historical component data that includes at least one of an aggregated energy component data at a substation level, a voltage component data at a substation level, and a weather data; determine energy usage at each of the plurality of user locations; compare the historical component data to the determined energy usage; and determine energy savings attributable to the system based on the results of the comparison of the historical component data to the determined energy usage. The voltage controller may be configured to determine energy savings attributable to the system based on a linear regression that removes effects of weather, load growth, or economic effects. The voltage controller may be further configured to increase the voltage set point when either the electrical power supply voltage component or the average user voltage component falls below a target voltage band.

According to a further aspect of the disclosure, a VCC system is provided that comprises: a substation configured to supply electrical power to a plurality of user locations; a smart meter located at one of the plurality of user locations and configured to generate smart meter data based on a measured component of electrical power received by the smart meter; and a voltage controller configured to control a voltage set point of the electrical power supplied by the substation based on the smart meter data. The smart meter may be configured to operate in a report-by-exception mode, which comprises sua sponte sending the smart meter data to the voltage controller when the measured component of electrical power is determined to be outside of a target component band.

The VCC system may further comprise: a second smart meter located at a second one of the plurality of user locations, the second smart meter being configured to generate second smart meter data based on a second measured component of electrical power received by the second smart meter, wherein the voltage controller is further configured to determine an average user voltage component by averaging the measured component of electrical power received by the smart meter and the second measured component of electrical power received by the second smart meter.

The substation may comprise: a load tap change transformer that adjusts the voltage set point value based on a load tap change coefficient; or a voltage regulator that adjusts the voltage set point value based on the energy delivery parameter. The substation may comprise a distribution bus that supplies the electrical power to the plurality of user locations, wherein an electrical power supply voltage component is measured on the distribution bus.

The voltage controller may be configured to increase the voltage set point when either the electrical power supply voltage component or the average user voltage component falls below a target voltage band. The voltage controller may be configured to adjust the voltage set point at a maximum rate of one load tap change step. The voltage controller may be configured to compare the measured component of electrical power received by the smart meter to a target component band and adjust the voltage set point based on a result of the comparison. The voltage controller may be configured to adjust the voltage set point based on the average user voltage component. The target component band may include a target voltage band, and the voltage controller may be configured to maintain the measured component of electrical power

received by the smart meter within the target voltage band based on the result of the comparison.

According to a still further aspect of the disclosure, a method is provided for controlling electrical power supplied to a plurality of user locations. The method comprises: receiving smart meter data from a first one of the plurality of user locations; and adjusting a voltage set point at a substation based on the smart meter data, wherein the smart meter data is sua sponte generated at the first one of the plurality of user locations when a measured component of electrical power that is supplied to the first one of the plurality of user locations is determined to be outside of a target component band.

The method may further comprise maintaining the average user voltage component within the target voltage band. The method may further comprise measuring a voltage component of the supplied electrical power on a distribution bus. The method may further comprise increasing the voltage set point when either the electrical power supply voltage component or an average user voltage component falls below the target component band. The method may further comprise: selecting said smart meter for monitoring; and creating a connection to said smart meter after receiving the smart meter data sent sua sponte by said smart meter while operating in a report-by-exception mode. The method may further comprise de-selecting another smart meter from a group of smart meters previously selected to be monitored. The method may further comprise terminating a connection to said another smart meter. The method may further comprise: storing historical component data that includes at least one of an aggregated energy component data at a substation level, a voltage component data at a substation level, and a weather data; determining energy usage at each of the plurality of user locations; comparing the historical component data to the determined energy usage; and determining energy savings attributable to the system based on the results of the comparison of the historical component data to the determined energy usage. The target component band may include a target voltage band. The method may further comprise: determining the target voltage band; and comparing an average user voltage component to the target voltage band.

The voltage set point may be adjusted based on the result of comparing the average user voltage component to the target voltage band. The sua sponte smart meter data received from the smart meter may be representative of a low voltage limiting level in the system.

According to a still further aspect of the disclosure, a computer readable medium is provided that tangibly embodies and includes a computer program for controlling electrical power supplied to a plurality of user locations. The computer program comprises a plurality of code sections, including: a receiving smart meter data code section that, when executed on a computer, causes receiving smart meter data from a first one of the plurality of user locations; and a voltage set point adjusting code section that, when executed on a computer, causes adjusting a voltage set point at a substation based on the smart meter data, wherein the smart meter data is sua sponte generated at the first one of the plurality of user locations when a measured component of electrical power that is supplied to the first one of the plurality of user locations is determined to be outside of a target component band.

The computer program may comprise an average user voltage component maintaining code section that, when executed on the computer, causes maintaining the average user voltage component within the target voltage band. The computer program may comprise a voltage component measuring code section that, when executed on the computer, causes a voltage component of the supplied electrical power to be measured on

US 8,437,883 B2

5   6

a distribution bus. The computer program may include a voltage set point increasing code section that, when executed on the computer, causes increasing the voltage set point when either the electrical power supply voltage component or an average user voltage component falls below the target component band. The computer program may comprise: a smart meter selection code section that, when executed on the computer, causes selecting said smart meter for monitoring; and a connection creation code section that, when executed on the computer, causes creating a connection to said smart meter after receiving the smart meter data sent sua sponte by said smart meter while operating in a report-by-exception mode. The computer program may comprise a smart meter de-selecting code section that, when executed on the computer, causes de-selecting another smart meter from a group of smart meters previously selected to be monitored. The computer program may comprise connection terminating code section that, when executed on the computer, causes terminating a connection to said another smart meter.

The computer program may comprise: a storing code section that, when executed on the computer, causes storing historical component data that includes at least one of an aggregated energy component data at a substation level, a voltage component data at a substation level, and a weather data; an energy usage determining code section that, when executed on the computer, causes determining energy usage at each of the plurality of user locations; a comparing code section that, when executed on the computer, causes comparing the historical component data to the determined energy usage; and an energy savings determination code section that, when executed on the computer, causes determining energy savings attributable to the system based on the results of the comparison of the historical component data to the determined energy usage. The target component band may include a target voltage band. The computer program may comprise: a target voltage band determining code section that, when executed on the computer, causes determining the target voltage band; and a comparing code section that, when executed on the computer, causes comparing an average user voltage component to the target voltage band. The voltage set point may be adjusted based on the result of comparing the average user voltage component to the target voltage band. The sua sponte smart meter data received from the smart meter may be representative of a low voltage limiting level in the system.

Additional features, advantages, and embodiments of the disclosure may be set forth or apparent from consideration of the detailed description and drawings. Moreover, it is to be understood that both the foregoing summary of the disclosure and the following detailed description are exemplary and intended to provide further explanation without limiting the scope of the disclosure as claimed.

BRIEF DESCRIPTION OF THE DRAWINGS

The accompanying drawings, which are included to provide a further understanding of the disclosure, are incorporated in and constitute a part of this specification, illustrate embodiments of the disclosure and together with the detailed description serve to explain the principles of the disclosure. No attempt is made to show structural details of the disclosure in more detail than may be necessary for a fundamental understanding of the disclosure and the various ways in which it may be practiced. In the drawings:

FIG. 1 shows an example of an electricity generation and distribution system, according to principles of the disclosure;

FIG. 2 shows an example of a voltage control and conservation (VCC) system, according to the principles of the disclosure;

FIG. 3 shows an example of a control screen that may be displayed on a regional operation center (ROC) computer, according to principles of the disclosure;

FIG. 4 shows an example of a voltage control and conservation (VCC) process according to principles of the disclosure;

FIG. 5A shows an example of a process for monitoring the voltage component and electrical energy received and measured at selected smart meters, according to principles of the disclosure;

FIG. 5B shows an example of a process for selecting a smart meter operating in a report-by-exception mode and de-selecting a previously selected smart meter, according to principles of the disclosure;

FIG. 6 shows an example of a graph of a voltage of electric power supplied to users versus a time of day, according to principles of the disclosure;

FIG. 7 shows an example of a graph of substation voltages of electric power produced by, for example, an LTC transformer at a substation, which may be associated with, for example, the information displayed on the control screen shown in FIG. 3;

FIG. 8 shows an example of data collected (including voltage and energy measurement) hourly by the DMS in the example of FIG. 7, before application of the voltage control according to the principles of the disclosure;

FIG. 9 shows an example of the data collected (including voltage and energy measurement) hourly by the DMS in the example of FIG. 7, after application of the voltage control according to the principles of the disclosure;

FIG. 10 shows an example of calculation data for hours 1-5 and the average for the full twenty-four hours in the example of FIGS. 7-9;

FIG. 11 shows an example where data may be collected for weather variables for the days before and after voltage control and/or conservation, according to principles of the disclosure;

FIG. 12 shows an example of an application of a paired test analysis process, according to principles of the disclosure;

FIG. 13 shows an example of a scatterplot of kW-per-customer days with VCC ON to kW-per-customer days with VCC OFF;

FIG. 14 shows an example of a summary chart for the data shown in FIG. 13, according to principles of the disclosure;

FIG. 15 shows an alternative example of a scatterplot of historical data before the VCC system is implemented, according to principles of the disclosure;

FIG. 16 shows an alternative example of a scatterplot of historical data after the VCC system is implemented, according to principles of the disclosure; and

FIG. 17 shows an alternative example of a summary chart, including 98% confidence intervals, according to principles of the disclosure.

The present disclosure is further described in the detailed description that follows.

DETAILED DESCRIPTION OF THE DISCLOSURE

The disclosure and the various features and advantageous details thereof are explained more fully with reference to the non-limiting embodiments and examples that are described and/or illustrated in the accompanying drawings and detailed in the following description. It should be noted that the features illustrated in the drawings are not necessarily drawn to

US 8,437,883 B2

7

8

scale, and features of one embodiment may be employed with other embodiments as the skilled artisan would recognize, even if not explicitly stated herein. Descriptions of well-known components and processing techniques may be omitted so as to not unnecessarily obscure the embodiments of the disclosure. The examples used herein are intended merely to facilitate an understanding of ways in which the disclosure may be practiced and to further enable those of skill in the art to practice the embodiments of the disclosure. Accordingly, the examples and embodiments herein should not be construed as limiting the scope of the disclosure. Moreover, it is noted that like reference numerals represent similar parts throughout the several views of the drawings.

A "computer", as used in this disclosure, means any machine, device, circuit, component, or module, or any system of machines, devices, circuits, components, modules, or the like, which are capable of manipulating data according to one or more instructions, such as, for example, without limitation, a processor, a microprocessor, a central processing unit, a general purpose computer, a super computer, a personal computer, a laptop computer, a palmtop computer, a notebook computer, a desktop computer, a workstation computer, a server, or the like, or an array of processors, microprocessors, central processing units, general purpose computers, super computers, personal computers, laptop computers, palmtop computers, notebook computers, desktop computers, workstation computers, servers, or the like.

A "server", as used in this disclosure, means any combination of software and/or hardware, including at least one application and/or at least one computer to perform services for connected clients as part of a client-server architecture. The at least one server application may include, but is not limited to, for example, an application program that can accept connections to service requests from clients by sending back responses to the clients. The server may be configured to run the at least one application, often under heavy workloads, unattended, for extended periods of time with minimal human direction. The server may include a plurality of computers configured, with the at least one application being divided among the computers depending upon the workload. For example, under light loading, the at least one application can run on a single computer. However, under heavy loading, multiple computers may be required to run the at least one application. The server, or any if its computers, may also be used as a workstation.

A "database", as used in this disclosure, means any combination of software and/or hardware, including at least one application and/or at least one computer. The database may include a structured collection of records or data organized according to a database model, such as, for example, but not limited to at least one of a relational model, a hierarchical model, a network model or the like. The database may include a database management system application (DBMS) as is known in the art. The at least one application may include, but is not limited to, for example, an application program that can accept connections to service requests from clients by sending back responses to the clients. The database may be configured to run the at least one application, often under heavy workloads, unattended, for extended periods of time with minimal human direction.

A "communication link", as used in this disclosure, means a wired and/or wireless medium that conveys data or information between at least two points. The wired or wireless medium may include, for example, a metallic conductor link, a radio frequency (RF) communication link, an Infrared (IR) communication link, an optical communication link, or the like, without limitation. The RF communication link may

include, for example, WiFi, WiMAX, IEEE 802.11, DECT, 0G, 1G, 2G, 3G or 4G cellular standards, Bluetooth, and the like.

The terms "including", "comprising" and variations thereof, as used in this disclosure, mean "including, but not limited to", unless expressly specified otherwise.

The terms "a", "an", and "the", as used in this disclosure, means "one or more", unless expressly specified otherwise.

Devices that are in communication with each other need not be in continuous communication with each other, unless expressly specified otherwise. In addition, devices that are in communication with each other may communicate directly or indirectly through one or more intermediaries.

Although process steps, method steps, algorithms, or the like, may be described in a sequential order, such processes, methods and algorithms may be configured to work in alternate orders. In other words, any sequence or order of steps that may be described does not necessarily indicate a requirement that the steps be performed in that order. The steps of the processes, methods or algorithms described herein may be performed in any order practical. Further, some steps may be performed simultaneously.

When a single device or article is described herein, it will be readily apparent that more than one device or article may be used in place of a single device or article. Similarly, where more than one device or article is described herein, it will be readily apparent that a single device or article may be used in place of the more than one device or article. The functionality or the features of a device may be alternatively embodied by one or more other devices which are not explicitly described as having such functionality or features.

A "computer-readable medium", as used in this disclosure, means any medium that participates in providing data (for example, instructions) which may be read by a computer. Such a medium may take many forms, including non-volatile media, volatile media, and transmission media. Non-volatile media may include, for example, optical or magnetic disks and other persistent memory. Volatile media may include dynamic random access memory (DRAM). Transmission media may include coaxial cables, copper wire and fiber optics, including the wires that comprise a system bus coupled to the processor. Transmission media may include or convey acoustic waves, light waves and electromagnetic emissions, such as those generated during radio frequency (RF) and infrared (IR) data communications. Common forms of computer-readable media include, for example, a floppy disk, a flexible disk, hard disk, magnetic tape, any other magnetic medium, a CD-ROM, DVD, any other optical medium, punch cards, paper tape, any other physical medium with patterns of holes, a RAM, a PROM, an EPROM, a FLASH-EEPROM, any other memory chip or cartridge, a carrier wave as described hereinafter, or any other medium from which a computer can read.

Various forms of computer readable media may be involved in carrying sequences of instructions to a computer. For example, sequences of instruction (i) may be delivered from a RAM to a processor, (ii) may be carried over a wireless transmission medium, and/or (iii) may be formatted according to numerous formats, standards or protocols, including, for example, WiFi, WiMAX, IEEE 802.11, DECT, 0G, 1G, 2G, 3G or 4G cellular standards, Bluetooth, or the like.

According to one non-limiting example of the disclosure, a voltage control and conservation (VCC) system **200** is provided (shown in FIG. **2**), which includes three subsystems, including an energy delivery (ED) system **300**, an energy control (EC) system **400** and an energy regulation (ER) system **500**. The VCC system **200** is configured to monitor

US 8,437,883 B2

9
10

energy usage at the ED system **300** and determine one or more energy delivery parameters C_{ED} at the EC system (or voltage controller) **400**. The EC system **400** may then provide the one or more energy delivery parameters C_{ED} to the ER system **500** to adjust the energy delivered to a plurality of users for maximum energy conservation.

The VCC system **200** may be integrated into, for example, an existing load curtailment plan of an electrical power supply system. The electrical power supply system may include an emergency voltage reduction plan, which may be activated when one or more predetermined events are triggered. The predetermined events may include, for example, an emergency, a short circuit, an overheating of electrical conductors, when the electrical power output from the transformer exceeds, for example, 80% of it power rating, or the like. The VCC system **200** is configured to yield to the load curtailment plan when the one or more predetermined events are triggered, allowing the load curtailment plan to be executed to reduce the voltage of the electrical power supplied to the plurality of users.

FIG. 1 shows an example of an electricity generation and distribution system **100**, according to principles of the disclosure. The electricity generation and distribution system **100** includes an electrical power generating station **110**, a generating step-up transformer **120**, a substation **130**, a plurality of step-down transformers **140**, **165**, **167**, and users **150**, **160**. The electrical power generating station **110** generates electrical power that is supplied to the step-up transformer **120**. The step-up transformer steps-up the voltage of the electrical power and supplies the stepped-up electrical power to an electrical transmission media **125**.

As seen in FIG. 1, the electrical transmission media may include wire conductors, which may be carried above ground by, for example, utility poles **127** and/or under ground by, for example, shielded conductors (not shown). The electrical power is supplied from the step-up transformer **120** to the substation **130** as electrical power $E_{In}(t)$, where the electrical power E_{In} in MegaWatts (MW) may vary as a function of time t. The substation **130** converts the received electrical power $E_{In}(t)$ to $E_{Supply}(t)$ and supplies the converted electrical power $E_{Supply}(t)$ to the plurality of users **150**, **160**. The substation **130** may adjustably transform the voltage component $V_{In}(t)$ of the received electrical power $E_{In}(t)$ by, for example, stepping-down the voltage before supplying the electrical power $E_{Supply}(t)$ to the users **150**, **160**. The electrical power $E_{Supply}(t)$ supplied from the substation **130** may be received by the step-down transformers **140**, **165**, **167** and supplied to the users **150**, **160** through a transmission medium **142**, **162**, such as, for example, but not limited to, underground electrical conductors (and/or above ground electrical conductors).

Each of the users **150**, **160** may include an Advanced Meter Infrastructure (AMI) **155**, **169**. The AMI **155**, **169** may be coupled to a Regional Operations Center (ROC) **180**. The ROC **180** may be coupled to the AMI **155**, **169**, by means of a plurality of communication links **175**, **184**, **188**, a network **170** and/or a wireless communication system **190**. The wireless communication system **190** may include, but is not limited to, for example, an RF transceiver, a satellite transceiver, and/or the like.

The network **170** may include, for example, at least one of the Internet, a local area network (LAN), a wide area network (WAN), a metropolitan area network (MAN), a personal area network (PAN), a campus area network, a corporate area network, a global area network (GAN), a broadband area network (BAN), or the like, any of which may be configured to communicate data via a wireless and/or a wired communication medium. The network **170** may be configured to

include a network topology such as, for example, a ring, a mesh, a line, a tree, a star, a bus, a full connection, or the like.

The AMI **155**, **169** may include any one or more of the following: A smart meter; a network interface (for example, a WAN interface, or the like); firmware; software; hardware; and the like. The smart meter may be configured to determine any one or more of the following: kilo-Watt-hours (kWh) delivered; kWh received; kWh delivered plus kWh received; kWh delivered minus kWh received; interval data; demand data; and the like. If the smart meter is a three phase meter, then the low phase voltage may be used in the average calculation. If the meter is a single phase meter, then the single voltage component will be averaged.

The AMI **155**, **169** may further include one or more collectors (shown in FIG. 2) configured to collect smart meter data from one or more smart meters tasked with, for example, measuring and reporting electric power delivery and consumption at one or more of the users **150**, **160**. Alternatively (or additionally), the one or more collectors may be located external to the users **150**, **160**, such as, for example, in a housing holding the step-down transformers **140**, **165**, **167**. Each of the collectors may be configured to communicate with the ROC **180**.

VCC System **200**

FIG. 2 shows an example of the VCC system **200**, according to principles of the disclosure. The VCC system **200** includes the ED system **300**, the EC system **400** and the ER system **500**, each of which is shown as a broken-line ellipse. The VCC system **200** is configured to monitor energy usage at the ED system **300**. The ED system **300** monitors energy usage at one or more users **150**, **160** (shown in FIG. 1) and sends energy usage information to the EC system **400**. The EC system **400** processes the energy usage information and generates one or more energy delivery parameters C_{ED}, which it sends to the ER system **500**. The ER system **500** receives the one or more energy delivery parameters C_{ED} and adjusts the electrical power $E_{Supply}(t)$ supplied to the users **150**, **160** based on the received energy delivery parameters C_{ED}.

The VCC system **200** minimizes power system losses, reduces user energy consumption and provides precise user voltage control. The VCC system **200** may include a closed loop process control application that uses user voltage data provided by the ED system **300** to control, for example, a voltage set point V_{SP} on a distribution circuit (not shown) within the ER system **500**. That is, the VCC system **200** may control the voltages $V_{Supply}(t)$ of the electrical power $E_{Supply}(t)$ supplied to the users **150**, **160**, by adjusting the voltage set point V_{SP} of the distribution circuit in the ER system **500**, which may include, for example, one or more load tap changing (LTC) transformers, one or more voltage regulators, or other voltage controlling equipment to maintain a tighter band of operation of the voltages $V_{Delivered}(t)$ of the electric power $E_{Delivered}(t)$ delivered to the users **150**, **160**, to lower power losses and facilitate efficient use of electrical power $E_{Delivered}(t)$ at the user locations **150** or **160**.

The VCC system **200** controls or adjusts the voltage $V_{Supply}(t)$ of the electrical power $E_{Supply}(t)$ supplied from the EC system **500** based on smart meter data, which includes measured voltage $V_{Meter}(t)$ data from the users **150**, **160** in the ED system **300**. The VCC system **200** may adjust the voltage set point V_{SP} at the substation or line regulator level in the ER system **500** by, for example, adjusting the LTC transformer (not shown), circuit regulators (not shown), or the like, to

US 8,437,883 B2

11   12

maintain the user voltages $V_{Meter}(t)$ in a target voltage band V_{Band-n}, which may include a safe nominal operating range.

The VCC system **200** is configured to maintain the electrical power $E_{Delivered}(t)$ delivered to the users **150, 160** within one or more voltage bands V_{Band-n}. For example, the energy may be delivered in two or more voltage bands V_{Band-n} substantially simultaneously, where the two or more voltage bands may be substantially the same or different. The value V_{Band-n} may be determined by the following expression [1]:

$$V_{Band-n} = V_{SP} + \Delta V \qquad [1]$$

where V_{Band-n} is a range of voltages, n is a positive integer greater than zero corresponding to the number of voltage bands V_{Band} that may be handled at substantially the same time, V_{SP} is the voltage set point value and ΔV is a voltage deviation range.

For example, the VCC system **200** may maintain the electrical power $E_{Delivered}(t)$ delivered to the users **150, 160** within a band V_{Band-1} equal to, for example, 111V to 129V for rural applications, where V_{SP} is set to 120V and ΔV is set to a deviation of seven-and-one-half percent (+/−7.5%). Similarly, the VCC system **200** may maintain the electrical power $E_{Delivered}(t)$ delivered to the users **150, 160** within a band V_{Band-2} equal to, for example, 114V to 126V for urban applications, where V_{SP} is set to 120V and ΔV is set to a deviation of five (+/−5%).

The VCC system **200** may maintain the electrical power $E_{Delivered}(t)$ delivered to the users **150, 160** at any voltage band V_{Band-n} usable by the users **150, 160**, by determining appropriate values for V_{SP} and ΔV. In this regard, the values V_{SP} and ΔV may be determined by the EC system **400** based on the energy usage information for users **150, 160**, received from the ED system **300**.

The EC system **400** may send the V_{SP} and ΔV values to the ER system **500** as energy delivery parameters C_{ED}, which may also include the value V_{Band-n}. The ER system **500** may then control and maintain the voltage $V_{Delivered}(t)$ of the electrical power $E_{Delivered}(t)$ delivered to the users **150, 160**, within the voltage band V_{Band-n}. The energy delivery parameters C_{ED} may further include, for example, load-tap-changer (LTC) control commands.

The VCC system **200** may further measure and validate energy savings by comparing energy usage by the users **150, 160** before a change in the voltage set point value V_{SP} (or voltage band V_{Band-n}) to the energy usage by the users **150, 160** after a change in the voltage set point value V_{SP} (or voltage band V_{Band-n}), according to principles of the disclosure. These measurements and validations may be used to determine the effect in overall energy savings by, for example, lowering the voltage $V_{Delivered}(t)$ of the electrical power $E_{Delivered}(t)$ delivered to the users **150, 160**, and to determine optimal delivery voltage bands V_{Band-n} for the energy power $E_{Delivered}(t)$ delivered to the users **150, 160**.

ER System **500**

The ER system **500** may communicate with the ED system **300** and/or EC system **400** by means of the network **170**. The ER system **500** is coupled to the network **170** and the EC system **400** by means of communication links **510** and **430**, respectively. The EC system **500** is also coupled to the ED system **300** by means of the power lines **340**, which may include communication links.

The ER system **500** includes a substation **530** which receives the electrical power supply $E_{In}(t)$ from, for example, the power generating station **110** (shown in FIG. 1) on a line **520**. The electrical power $E_{In}(t)$ includes a voltage $V_{In}(t)$

component and a current $I_{In}(t)$ component. The substation **530** adjustably transforms the received electrical power $E_{In}(t)$ to, for example, reduce (or step-down) the voltage component $V_{In}(t)$ of the electrical power $E_{In}(t)$ to a voltage value $V_{Supply}(t)$ of the electrical power $E_{Supply}(t)$ supplied to the plurality of smart meters **330** on the power supply lines **340**.

The substation **530** may include a transformer (not shown), such as, for example, a load tap change (LTC) transformer. In this regard, the substation **530** may further include an automatic tap changer mechanism (not shown), which is configured to automatically change the taps on the LTC transformer. The tap changer mechanism may change the taps on the LTC transformer either on-load (on-load tap changer, or OLTC) or off-load, or both. The tap changer mechanism may be motor driven and computer controlled. The substation **530** may also include a buck/boost transformer to adjust and maximize the power factor of the electrical power $E_{Delivered}(t)$ supplied to the users on power supply lines **340**.

Additionally (or alternatively), the substation **530** may include one or more voltage regulators, or other voltage controlling equipment, as known by those having ordinary skill in the art, that may be controlled to maintain the output voltage component $V_{Supply}(t)$ of the electrical power $E_{Supply}(t)$ at a predetermined voltage value or within a predetermined range of voltage values.

The substation **530** receives the energy delivery parameters C_{ED} from the EC system **400** on the communication link **430**. The energy delivery parameters C_{ED} may include, for example, load tap coefficients when an LTC transformer is used to step-down the input voltage component $V_{In}(t)$ of the electrical power $E_{In}(t)$ to the voltage component $V_{Supply}(t)$ of the electrical power $E_{Supply}(t)$ supplied to the ED system **300**. In this regard, the load tap coefficients may be used by the ER system **500** to keep the voltage component $V_{Supply}(t)$ on the low-voltage side of the LTC transformer at a predetermined voltage value or within a predetermined range of voltage values.

The LTC transformer may include, for example, seventeen or more steps (thirty-five or more available positions), each of which may be selected based on the received load tap coefficients. Each change in step may adjust the voltage component $V_{Supply}(t)$ on the low voltage side of the LTC transformer by as little as, for example, about five-thousandths (0.5%), or less.

Alternatively, the LTC transformer may include fewer than seventeen steps. Similarly, each change in step of the LTC transformer may adjust the voltage component $V_{Supply}(t)$ on the low voltage side of the LTC transformer by more than, for example, about five-thousandths (0.5%).

The voltage component $V_{Supply}(t)$ may be measured and monitored on the low voltage side of the LTC transformer by, for example, sampling or continuously measuring the voltage component $V_{Supply}(t)$ of the stepped-down electrical power $E_{Supply}(t)$ and storing the measured voltage component $V_{Supply}(t)$ values as a function of time t in a storage (not shown), such as, for example, a computer readable medium. The voltage component $V_{Supply}(t)$ may be monitored on, for example, a substation distribution bus, or the like. Further, the voltage component $V_{Supply}(t)$ may be measured at any point where measurements could be made for the transmission or distribution systems in the ER system **500**.

Similarly, the voltage component $V_{In}(t)$ of the electrical power $E_{In}(t)$ input to the high voltage side of the LTC transformer may be measured and monitored. Further, the current component $I_{Supply}(t)$ of the stepped-down electrical power $E_{Supply}(t)$ and the current component $I_{In}(t)$ of the electrical power $E_{In}(t)$ may also be measured and monitored. In this

US 8,437,883 B2

13   14

regard, a phase difference $\phi_{In}(t)$ between the voltage $V_{In}(t)$ and current $I_{In}(t)$ components of the electrical power $E_{In}(t)$ may be determined and monitored. Similarly, a phase difference $\phi_{Supply}(t)$ between the voltage $V_{Supply}(t)$ and current $I_{Supply}(t)$ components of the electrical energy supply $E_{Supply}(t)$ may be determined and monitored.

The ER system **500** may provide electrical energy supply status information to the EC system **400** on the communication links **430** or **510**. The electrical energy supply information may include the monitored voltage component $V_{Supply}(t)$. The electrical energy supply information may further include the voltage component $V_{In}(t)$, current components $I_{In}(t)$, $I_{Supply}(t)$, and/or phase difference values $\phi_{In}(t)$, $\phi_{Supply}(t)$, as a function of time t. The electrical energy supply status information may also include, for example, the load rating of the LTC transformer.

The electrical energy supply status information may be provided to the EC system **400** at periodic intervals of time, such as, for example, every second, 5 sec., 10 sec., 30 sec., 60 sec., 120 sec., 600 sec., or any other value within the scope and spirit of the disclosure, as determined by one having ordinary skill in the art. The periodic intervals of time may be set by the EC system **400** or the ER system **500**. Alternatively, the electrical energy supply status information may be provided to the EC system **400** or ER system **500** intermittently.

Further, the electrical energy supply status information may be forwarded to the EC system **400** in response to a request by the EC system **400**, or when a predetermined event is detected. The predetermined event may include, for example, when the voltage component $V_{Supply}(t)$ changes by an amount greater (or less) than a defined threshold value $V_{SupplyThreshold}$ (for example, 130V) over a predetermined interval of time, a temperature of one or more components in the ER system **500** exceeds a defined temperature threshold, or the like.

ED System 300

The ED system **300** includes a plurality of smart meters **330**. The ED system **300** may further include at least one collector **350**, which is optional. The ED system **300** may be coupled to the network **170** by means of a communication link **310**. The collector **350** may be coupled to the plurality of smart meters **330** by means of a communication link **320**. The smart meters **330** may be coupled to the ER system **500** by means of one or more power supply lines **340**, which may also include communication links.

Each smart meter **330** is configured to measure, store and report energy usage data by the associated users **150**, **160** (shown in FIG. **1**). Each smart meter **330** is further configured to measure and determine energy usage at the users **150**, **160**, including the voltage component $V_{Meter}(t)$ and current component $I_{Meter}(t)$ of the electrical power $E_{Meter}(t)$ used by the users **150**, **160**, as a function of time. The smart meters **330** may measure the voltage component $V_{Meter}(t)$ and current component $I_{Meter}(t)$ of the electrical power $E_{Meter}(t)$ at discrete times t_s, where s is a sampling period, such as, for example, s=5 sec., 10 sec., 30 sec., 60 sec., 300 sec., 600 sec., or more. For example, the smart meters **330** may measure energy usage every, for example, minute ($t_{60\,sec}$), five minutes ($t_{300\,sec}$), ten minutes ($t_{600\,sec}$), or more, or at time intervals variably set by the smart meter **330** (for example, using a random number generator).

The smart meters **330** may average the measured voltage $V_{Meter}(t)$ and/or $I_{Meter}(t)$ values over predetermined time intervals (for example, 5 min., 10 min., 30 min., or more). The smart meters **330** may store the measured electrical power

usage $E_{Meter}(t)$, including the measured voltage component $V_{Meter}(t)$ and/or current component $I_{Meter}(t)$ as smart meter data in a local (or remote) storage (not shown), such as, for example, a computer readable medium.

Each smart meter **330** is also capable of operating in a "report-by-exception" mode for any voltage $V_{Meter}(t)$, current $I_{Meter}(t)$, or energy usage $E_{Meter}(t)$ that falls outside of a target component band. The target component band may include, a target voltage band, a target current band, or a target energy usage band. In the "report-by-exception" mode, the smart meter **330** may sua sponte initiate communication and send smart meter data to the EC system **400**. The "report-by-exception" mode may be used to reconfigure the smart meters **330** used to represent, for example, the lowest voltages on the circuit as required by changing system conditions.

The smart meter data may be periodically provided to the collector **350** by means of the communication links **320**. Additionally, the smart meters **330** may provide the smart meter data in response to a smart meter data request signal received from the collector **350** on the communication links **320**.

Alternatively (or additionally), the smart meter data may be periodically provided directly to the EC system **400** (for example, the MAS **460**) from the plurality of smart meters, by means of, for example, communication links **320**, **410** and network **170**. In this regard, the collector **350** may be bypassed, or eliminated from the ED system **300**. Furthermore, the smart meters **330** may provide the smart meter data directly to the EC system **400** in response to a smart meter data request signal received from the EC system **400**. In the absence of the collector **350**, the EC system (for example, the MAS **460**) may carry out the functionality of the collector **350** described herein.

The request signal may include, for example, a query (or read) signal and a smart meter identification signal that identifies the particular smart meter **330** from which smart meter data is sought. The smart meter data may include the following information for each smart meter **130**, including, for example, kilo-Watt-hours (kWh) delivered data, kWh received data, kWh delivered plus kWh received data, kWh delivered minus kWh received data, voltage level data, current level data, phase angle between voltage and current, kVar data, time interval data, demand data, and the like.

Additionally, the smart meters **330** may send the smart meter data to the meter automation system server MAS **460**. The smart meter data may be sent to the MAS **460** periodically according to a predetermined schedule or upon request from the MAS **460**.

The collector **350** is configured to receive the smart meter data from each of the plurality of smart meters **330** via the communication links **320**. The collector **350** stores the received smart meter data in a local storage (not shown), such as, for example, a computer readable medium. The collector **350** compiles the received smart meter data into a collector data. In this regard, the received smart meter data may be aggregated into the collector data based on, for example, a geographic zone in which the smart meters **330** are located, a particular time band (or range) during which the smart meter data was collected, a subset of smart meters **330** identified in a collector control signal, and the like. In compiling the received smart meter data, the collector **350** may average the voltage component $V_{Meter}(t)$ values received in the smart meter data from all (or a subset of all) of the smart meters **330**.

The EC system **400** is able to select or alter a subset of all of the smart meters **330** to be monitored for predetermined time intervals, which may include for example 15 minute intervals. It is noted that the predetermined time intervals may

US 8,437,883 B2

15

be shorter or longer than 15 minutes. The subset of all of the smart meters **330** is selectable and can be altered by the EC system **400** as needed to maintain minimum level control of the voltage $V_{Supply}(t)$ supplied to the smart meters **330**.

The collector **350** may also average the electrical power $E_{Meter}(t)$ values received in the smart meter data from all (or a subset of all) of the smart meters **330**. The compiled collector data may be provided by the collector **350** to the EC system **400** by means of the communication link **310** and network **170**. For example, the collector **350** may send the compiled collector data to the MAS **460** (or ROC **490**) in the EC system **400**.

The collector **350** is configured to receive collector control signals over the network **170** and communication link **310** from the EC system **400**. Based on the received collector control signals, the collector **350** is further configured to select particular ones of the plurality of smart meters **330** and query the meters for smart meter data by sending a smart meter data request signal to the selected smart meters **330**. The collector **350** may then collect the smart meter data that it receives from the selected smart meters **330** in response to the queries. The selectable smart meters **330** may include any one or more of the plurality of smart meters **330**. The collector control signals may include, for example, an identification of the smart meters **330** to be queried (or read), time(s) at which the identified smart meters **330** are to measure the $V_{Meter}(t)$, $I_{Meter}(t)$, $E_{Meter}(t)$ and/or $\phi_{Meter}(t)$ ($\phi_{Meter}(t)$ is the phase difference between the voltage $V_{Meter}(t)$ and current $I_{Meter}(t)$ components of the electrical power $E_{Meter}(t)$ measured at the identified smart meter **330**), energy usage information since the last reading from the identified smart meter **330**, and the like. The collector **350** may then compile and send the compiled collector data to the MAS **460** (and/or ROC **490**) in the EC system **400**.

EC System 400

The EC system **400** may communicate with the ED system **300** and/or ER system **500** by means of the network **170**. The EC system **400** is coupled to the network **170** by means of one or more communication links **410**. The EC system **400** may also communicate directly with the ER system **500** by means of a communication link **430**.

The EC system **400** includes the MAS **460**, a database (DB) **470**, a distribution management system (DMS) **480**, and a regional operation center (ROC) **490**. The ROC **490** may include a computer (ROC computer) **495**, a server (not shown) and a database (not shown). The MAS **460** may be coupled to the DB **470** and DMS **480** by means of communication links **420** and **440**, respectively. The DMS **480** may be coupled to the ROC **490** and ER SYSTEM **500** by means of the communication link **430**. The database **470** may be located at the same location as (for example, proximate to, or within) the MAS **460**, or at a remote location that may be accessible via, for example, the network **170**.

The EC system **400** is configured to de-select, from the subset of monitored smart meters **330**, a smart meter **330** that the EC system **400** previously selected to monitor, and select the smart meter **330** that is outside of the subset of monitored smart meters **330**, but which is operating in the report-by-exception mode. The EC system **400** may carry out this change after receiving the sua sponte smart meter data from the non-selected smart meter **330**. In this regard, the EC system **400** may remove or terminate a connection to the de-selected smart meter **330** and create a new connection to the newly selected smart meter **330** operating in the report-by-exception mode. The EC system **400** is further configured

16

to select any one or more of the plurality of smart meters **330** from which it receives smart meter data comprising, for example, the lowest measured voltage component $V_{Meter}(t)$, and generate an energy delivery parameter C_{ED} based on the smart meter data received from the smart meter(s) **330** that provide the lowest measured voltage component $V_{Meter}(t)$.

The MAS **460** may include a computer (not shown) that is configured to receive the collector data from the collector **350**, which includes smart meter data collected from a selected subset (or all) of the smart meters **330**. The MAS **460** is further configured to retrieve and forward smart meter data to the ROC **490** in response to queries received from the ROC **490**. The MAS **460** may store the collector data, including smart meter data in a local storage and/or in the DB **470**.

The DMS **480** may include a computer that is configured to receive the electrical energy supply status information from the substation **530**. The DMS **480** is further configured to retrieve and forward measured voltage component $V_{Meter}(t)$ values and electrical power $E_{Meter}(t)$ values in response to queries received from the ROC **490**. The DMS **480** may be further configured to retrieve and forward measured current component $I_{Meter}(t)$ values in response to queries received from the ROC **490**. The DMS **480** also may be further configured to retrieve all "report-by-exception" voltages $V_{Meter}(t)$ from the smart meters **330** operating in the "report-by-exception" mode and designate the voltages $V_{Meter}(t)$ as one of the control points to be continuously read at predetermined times (for example, every 15 minutes, or less (or more), or at varying times). The "report-by-exception voltages $V_{Meter}(t)$ may be used to control the EC **500** set points.

The DB **470** may include a plurality of relational databases (not shown). The DB **470** includes a large number of records that include historical data for each smart meter **330**, each collector **350**, each substation **530**, and the geographic area(s) (including latitude, longitude, and altitude) where the smart meters **330**, collectors **350**, and substations **530** are located.

For instance, the DB **470** may include any one or more of the following information for each smart meter **330**, including: a geographic location (including latitude, longitude, and altitude); a smart meter identification number; an account number; an account name; a billing address; a telephone number; a smart meter type, including model and serial number; a date when the smart meter was first placed into use; a time stamp of when the smart meter was last read (or queried); the smart meter data received at the time of the last reading; a schedule of when the smart meter is to be read (or queried), including the types of information that are to be read; and the like.

The historical smart meter data may include, for example, the electrical power $E_{Meter}(t)$ used by the particular smart meter **330**, as a function of time. Time t may be measured in, for example, discrete intervals at which the electrical power E_{Meter} magnitude (kWh) of the received electrical power $E_{Meter}(t)$ is measured or determined at the smart meter **330**. The historical smart meter data includes a measured voltage component $V_{Meter}(t)$ of the electrical energy $E_{Meter}(t)$ received at the smart meter **330**. The historical smart meter data may further include a measured current component $I_{Meter}(t)$ and/or phase difference $\phi_{Meter}(t)$ of the electrical power $E_{Meter}(t)$ received at smart meter **330**.

As noted earlier, the voltage component $V_{Meter}(t)$ may be measured at a sampling period of, for example, every five seconds, ten seconds, thirty seconds, one minute, five minutes, ten minutes, fifteen minutes, or the like. The current component $I_{Meter}(t)$ and/or the received electrical power $E_{Meter}(t)$ values may also be measured at substantially the same times as the voltage component $V_{Meter}(t)$.

US 8,437,883 B2

17   18

Given the low cost of memory, the DB **470** may include historical data from the very beginning of when the smart meter data was first collected from the smart meters **330** through to the most recent smart meter data received from the smart meter **330s**.

The DB **470** may include a time value associated with each measured voltage component $V_{Meter}(t)$, current component $I_{Meter}(t)$, phase component $\phi_{Meter}(t)$ and/or electrical power $E_{Meter}(T)$, which may include a timestamp value generated at the smart meter **330**. The timestamp value may include, for example, a year, a month, a day, an hour, a minute, a second, and a fraction of a second. Alternatively, the timestamp may be a coded value which may be decoded to determine a year, a month, a day, an hour, a minute, a second, and a fraction of a second, using, for example, a look up table. The ROC **490** and/or smart meters **330** may be configured to receive, for example, a WWVB atomic clock signal transmitted by the U.S. National Institute of Standards and Technology (NIST), or the like and synchronize its internal clock (not shown) to the WWVB atomic clock signal.

The historical data in the DB **470** may further include historical collector data associated with each collector **350**. The historical collector data may include any one or more of the following information, including, for example: the particular smart meters **330** associated with each collector **350**; the geographic location (including latitude, longitude, and altitude) of each collector **350**; a collector type, including model and serial number; a date when the collector **350** was first placed into use; a time stamp of when collector data was last received from the collector **350**; the collector data that was received; a schedule of when the collector **350** is expected to send collector data, including the types of information that are to be sent; and the like.

The historical collector data may further include, for example, an external temperature value $T_{Collector}(t)$ measured outside of each collector **350** at time t. The historical collector data may further include, for example, any one or more of the following for each collector **350**: an atmospheric pressure value $P_{Collector}(t)$ measured proximate the collector **350** at time t; a humidity value $H_{Collector}(t)$ measured proximate the collector **350** at time t; a wind vector value $W_{Collector}(t)$ measured proximate the collector **350** at time t, including direction and magnitude of the measured wind; a solar irradiant value $L'_{Collector}(t)$ (kW/m^2) measured proximate the collector **350** at time t; and the like.

The historical data in the DB **470** may further include historical substation data associated with each substation **530**. The historical substation data may include any one or more of the following information, including, for example: the identifications of the particular smart meters **330** supplied with electrical energy $E_{Supply}(t)$ by the substation **530**; the geographic location (including latitude, longitude, and altitude) of the substation **530**; the number of distribution circuits; the number of transformers; a transformer type of each transformer, including model, serial number and maximum Megavolt Ampere (MVA) rating; the number of voltage regulators; a voltage regulator type of each voltage regulator, including model and serial number; a time stamp of when substation data was last received from the substation **530**; the substation data that was received; a schedule of when the substation **530** is expected to provide electrical energy supply status information, including the types of information that are to be provided; and the like.

The historical substation data may include, for example, the electrical power $E_{Supply}(t)$ supplied to each particular smart meter **330**, where $E_{Supply}(t)$ is measured or determined at the output of the substation **530**. The historical substation data includes a measured voltage component $V_{Supply}(t)$ of the supplied electrical power $E_{Supply}(t)$, which may be measured, for example, on the distribution bus (not shown) from the transformer. The historical substation data may further include a measured current component $I_{Supply}(t)$ of the supplied electrical power $E_{Supply}(t)$. As noted earlier, the voltage component $V_{Supply}(t)$, the current component $I_{Supply}(t)$, and/or the electrical power $E_{Supply}(t)$ may be measured at a sampling period of, for example, every five seconds, ten seconds, thirty seconds, a minute, five minutes, ten minutes, or the like. The historical substation data may further include a phase difference value $\phi_{Supply}(t)$ between the voltage $V_{Supply}(t)$ and current $I_{Supply}(t)$ signals of the electrical power $E_{Supply}(t)$, which may be used to determine the power factor of the electrical power $E_{Supply}(t)$ supplied to the smart meters **330**.

The historical substation data may further include, for example, the electrical power $E_{In}(t)$ received on the line **520** at the input of the substation **530**, where the electrical power $E_{In}(t)$ is measured or determined at the input of the substation **530**. The historical substation data may include a measured voltage component $V_{In}(t)$ of the received electrical power $E_{In}(t)$, which may be measured, for example, at the input of the transformer. The historical substation data may further include a measured current component $I_{In}(t)$ of the received electrical power $E_{In}(t)$. As noted earlier, the voltage component $V_{In}(t)$, the current component $I_{In}(t)$, and/or the electrical power $E_{In}(t)$ may be measured at a sampling period of, for example, every five seconds, ten seconds, thirty seconds, a minute, five minutes, ten minutes, or the like. The historical substation data may further include a phase difference $\phi_{In}(t)$ between the voltage component $V_{In}(t)$ and current component $I_{In}(t)$ of the electrical power $E_{In}(t)$. The power factor of the electrical power $E_{In}(t)$ may be determined based on the phase difference $\phi_{In}(t)$.

According to an aspect of the disclosure, the EC system **400** may save aggregated kW data at the substation level, voltage data at the substation level, and weather data to compare to energy usage per smart meter **330** to determine the energy savings from the VCC system **200**, and using linear regression to remove the affects of weather, load growth, economic effects, and the like, from the calculation.

In the VCC system **200**, control may be initiated from, for example, the ROC computer **495**. In this regard, a control screen **305** may be displayed on the ROC computer **495**, as shown, for example, in FIG. **3**. The control screen **305** may correspond to data for a particular substation **530** (for example, the TRABUE SUBSTATION) in the ER system **500**. The ROC computer **495** can control and override (if necessary), for example, the substation **530** load tap changing transformer based on, for example, the smart meter data received from the ED system **300** for the users **150**, **160**. The ED system **300** may determine the voltages of the electrical power supplied to the user locations **150**, **160**, at predetermined (or variable) intervals, such as, e.g., on average each 15 minutes, while maintaining the voltages within required voltage limits.

For system security, the substation **530** may be controlled through the direct communication link **430** from the ROC **490** and/or DMS **480**.

Furthermore, an operator can initiate a voltage control program on the ROC computer **490**, overriding the controls, if necessary, and monitoring a time it takes to read the user voltages $V_{Meter}(t)$ being used for control of, for example, the substation LTC transformer (not shown) in the ER system **500**.

FIG. **4** shows an example of a voltage control and conservation (VCC) process according to principles of the disclo-

US 8,437,883 B2

19

sure. The VCC process may be carried out by, for example, but not limited to, the VCC system **200** shown in FIG. **2**.

Referring to FIGS. **2** and **4**, a target voltage band V_{Band-n} may be determined for the voltage component $V_{Meter}(t)$ of the electrical power $E_{Meter}(t)$ received and measured at the smart meters **330** (Step **610**). The target voltage band V_{Band-n} may be determined by setting a voltage set point value V_{SP} and a permissible voltage deviation range ΔV according to the expression [1] $V_{Band-n} = V_{SP} + \Delta V$. For instance, the voltage set point V_{SP} value may be set to 120V with a permissible voltage deviation of ΔV of five percent (+/−5%) for the target voltage band V_{Band-1}. In this example, the target voltage band V_{Band-1} will be from about 114V (i.e., 120V−(120V×0.050)) to about 126V (i.e., 120V+(120V×0.050)).

The voltage component $V_{Supply}(t)$ and electrical power $E_{Supply}(t)$ values measured at substation **530** may be retrieved from the DMS **480** (Step **620**). The current, or most recent voltage component $V_{Meter}(t)$ and electrical power $E_{Meter}(t)$ values received and measured at the selected subset of the plurality of smart meters **330** may be retrieved from the MAS **460** (or a local storage, such as, for example, a computer readable medium, in the ROC **490**) (Step **630**). The current, or most recent voltage component $V_{Meter}(t)$ and electrical power $E_{Meter}(t)$ values may have been measured by the select subset of smart meters **330** and forwarded to the MAS **460** via the collector **350**, as described above.

Alternatively, the current, or most recent voltage component $V_{Meter}(t)$ and electrical power $E_{Meter}(t)$ values may have been retrieved directly from the collector **350** or the selected subset of the smart meters **330** (Step **630**).

The current, or most recent voltage component $V_{Meter}(t)$ and electrical power subset $E_{Meter}(t)$ values may have been measured at the selected et of smart meters **330** in response to a smart meter data request signal received from the collector **350**. The collector **350** may have sent the smart meter data request signal in response to a collector control signal received from the MAS **460** (or the ROC **490**).

The current, or most recent voltage component $V_{Meter}(t)$ values may be averaged for the selected number of smart meters **330** to determine an average voltage component $V_{Meter-Avg}(t)$ value for the electrical power delivered to the selected smart meters **330**. This average voltage component $V_{Meter-Avg}(t)$ value may then be compared to the target voltage band V_{Band-n} to determine whether the average voltage component $V_{Meter-Avg}(t)$ value is within the target voltage band V_{Band-n} (Step **650**).

If the average voltage component $V_{Meter-Avg}(t)$ value is outside of the target voltage band V_{Band-n}, then a determination is made to change the set point voltage V_{SP} of the voltage component $V_{Supply}(t)$ output by the substation **530** (YES at Step **660**). Energy delivery parameters C_{ED} may be generated and sent to the substation **530** to adjust the set point voltage V_{SP} of the output voltage component $V_{Supply}(t)$ (Step **670**). A new voltage set point voltage V_{SP} value may be calculated by the DMS **480**. Where a LTC transformer is used, the voltage set point voltage V_{SP} value may be increased (or decreased) at a maximum rate of, for example, one volt about every, for example, fifteen minutes (Note: for example, a 0.625% voltage change per step in a LTC transformer). It is noted that the voltage set point voltage V_{SP} value may be increased (or decreased) at a rate of, for example, a fraction of a volt, or multiple volts at one time. The energy delivery parameters C_{ED} may include, for example, load tap coefficients. The set point voltage V_{SP} may be adjusted up (or down) by, for example, a fraction of a Volt (e.g., 0.01V, 0.02V, . . . , 0.1V, 0.2V, . . . , 1.0V, . . . , or the like).

20

Furthermore, when either the $V_{Supply}(t)$ or the $V_{Meter-Avg}(t)$ voltage components reach or fall below a predetermined minimum voltage range (for example, about 118V to about 119V), the set point voltage V_{SP} may be increased. When the voltage set point V_{SP} is raised, the $V_{Supply}(t)$ or the $V_{Meter-Avg}(t)$ voltage components should remain in a higher voltage band for, e.g., twenty-four hours before the voltage set point V_{SP} may be lowered again.

If the average voltage component $V_{Meter-Avg}(t)$ value is within the target voltage band V_{Band-n}, then a determination is made not to change the set point voltage V_{SP} of the voltage component $V_{Supply}(t)$ output by the substation **530** (NO at Step **660**), and a determination may be made whether to end the VCC process (Step **680**). If a determination is made not to end the VCC process (NO at Step **680**), the VCC process repeats.

According to an aspect of the disclosure, a computer readable medium is provided containing a computer program, which when executed on, for example, the ROC **495** (shown in FIG. **2**), causes the VCC process according to FIG. **4** to be carried out. The computer program may be tangibly embodied in the computer readable medium, comprising a code segment or code section for each of the Steps **610** through **680**.

FIG. **5A** shows an example of a process for monitoring the voltage component $V_{Meter}(t)$ and electrical power $E_{Meter}(t)$ received and measured at selected smart meters **330**, according to an aspect of disclosure.

Referring to FIGS. **2** and **5A**, initially a subset of smart meters **330** is selected from the smart meters **330** that are coupled to the power lines **340**, which are supplied with the electrical energy $E_{Supply}(t)$ out from the substation **530** (Step **710**). The subset may include, for example, one or more (or all) of the smart meters **330** that are selected randomly or based on predetermined criteria. The predetermined criteria may include, for example, historical smart meter data, weather conditions, geographic area, solar irradiation, historical energy usage associated with particular smart meters **330**, and the like. The smart meters **330** may be selected, for example, at the ROC **490** or MAS **460**.

A schedule may be generated to obtain smart meter data from the selected subset of smart meters **330** (Step **720**). The schedule may include, for example, measuring the received voltage component $V_{Meter}(t)$ and electrical power $E_{Meter}(t)$ every, for example, five seconds, ten seconds, thirty seconds, one minute, five minutes, ten minutes, fifteen minutes, or the like, at the selected subset of smart meters **330**. The generated schedule is provided to the collector **350** that is associated with the selected subset of smart meters **330** as part of a collector control signal (Step **730**). The collector control signal may be generated at, for example, the ROC **490** or MAS **460** and sent to the collector **350** via communication link **410** and network **170**.

The collector **350**, based on the provided collector control signal or a previously received schedule, may send a smart meter data request signal to the selected subset of smart meters **330** via communication links **320**. The smart meter data request signal may include, for example, the schedule provided in the collector control signal. The schedule may be stored at the selected subset of smart meters **330** and used by the smart meters **330** to control monitoring and reporting of the received voltage component $V_{Meter}(t)$ and electrical power $E_{Meter}(t)$ for the associated user **150** (**160**).

The collector **350** receives the reported smart meter data, including the voltage component $V_{Meter}(t)$ and electrical energy $E_{Meter}(t)$ for the associated user **150** (**160**), from the selected subset of smart meters **330** via communication links

US 8,437,883 B2

<table>
<tr><td>21</td><td>22</td></tr>
</table>

320. The collector 350 compiles the received smart meter data, generating collector data and sending the collector data to the EC system 400.

The collector data is received from the collector 350 (Step 740) and stored locally (or remotely) in the EC system 400 (Step 750). In particular, the received collector data is stored locally in, for example, the ROC 490, the MAS 460 and/or the DB 470.

According to an aspect of the disclosure, a computer readable medium is provided containing a computer program, which when executed on, for example, the ROC 495 (shown in FIG. 2), causes the process for monitoring the voltage component and electrical power to be carried out according to FIG. 5A. The computer program may be tangibly embodied in the computer readable medium, comprising a code segment or code section for each of the Steps 710 through 750.

FIG. 5B shows an example of a process for selecting a smart meter 330 operating in a report-by-exception mode and de-selecting a previously selected smart meter, according to principles of the disclosure.

Referring to FIG. 2 and FIG. 5B, the EC system 400 is configured to listen or monitor for sua sponte smart meter data that may be received from one or more of the smart meters 330 operating in the report-by-exception mode (Step 760). If sua sponte smart meter data is received from a particular smart meter 330 (YES, at Step 760), then the EC system 400 will proceed to select that particular smart meter 330 (Step 765) and create a communication link to the smart meter 330 (Step 770), otherwise the EC system 400 continues to monitor for sua sponte smart meter data (NO, at Step 760). The EC system 400 de-selects a previously selected smart meter 330 (Step 775), which was selected as part of the subset smart meters 330 to be monitored from the plurality of smart meters 330, and terminates the communication link to the de-selected smart meter 330 (Step 780). The EC system 400 may use the sua sponte smart meter data to determine a voltage set point and provide the voltage set point to the ER system 500 to adjust the voltage set point (Step 785).

According to an aspect of the disclosure, a computer readable medium is provided containing a computer program, which when executed on, for example, the ROC 495 (shown in FIG. 2), causes the process for selecting a smart meter 330 operating in a report-by-exception mode and de-selecting a previously selected smart meter. The computer program may be tangibly embodied in the computer readable medium, comprising a code segment or code section for each of the Steps 760 through 785.

FIG. 6 shows an example of a graph of a voltage of electric power supplied to users 150, 160, versus a time of day, according to principles of the disclosure. In particular, the upper waveform 805 shows an example of voltage fluctuations in the electrical power delivered to the users 150, 160, without the VCC system 200. The lower waveform 808 shows an example of voltage fluctuations in the electric power delivered to users 150, 160, with the VCC system 200. The area 807 between the upper waveform 805 and lower waveform 808 corresponds to the energy saved using the VCC system 200.

As seen in FIG. 6, the lower waveform 808 includes a tighter range (lower losses) of voltage fluctuations compared to the upper waveform 805, which experiences higher voltage fluctuations and increased losses, resulting in substantially reduced power losses for the lower waveform 808. For example, the voltage 805 may fluctuate between about 114V and about 127V. Whereas, in the VCC system 200, the voltage waveform 808 fluctuation may be reduced to, for example, between about 114V and about 120V. As seen in the graph,

the VCC system 200 may provide conservation through, for example, avoided energy imports and behind-the-meter savings. Further, the VCC system 200 may provide high confidence level of savings without having to depend on the actions of the users 150, 160.

FIG. 7 shows an example of a waveform 810 of substation voltages V_{Supply}(t) of electric power produced by, for example, an LTC transformer at the substation 530, which may be associated with, for example, the information displayed on the control screen 305 shown in FIG. 3. A waveform 820 shows an average of, for example, twenty lowest level (or worst case) user voltages V_{Meter}(t) (for example, the ten worst voltages on one distribution circuit averaged with the ten worst voltages on another distribution circuit) monitored at any one time on two distribution circuits that supply, for example, six-thousand-four-hundred users 150, 160 (shown in FIG. 1) with electrical power during a period of time. In particular, the graph 810 shows an example of voltage fluctuations (for example, an average of voltage 812 fluctuations and voltage 814 fluctuations on the pair of circuits, respectively) in the electrical power produced by the substation 530 (for example, the TRABUE SUBSTATION in FIG. 3) and the voltage 820 fluctuations (for example, on the pair of circuits) in the electrical power delivered to the users 150, 160.

The waveforms 810 and 820 prior to time t_o show an example of voltage fluctuations in the electrical power E_{Supply}(t) supplied by the substation 530 and electrical power E_{Meter}(t) received by the users 150, 160, without the VCC system 200. The waveforms 810 and 820 after time t_o show an example of voltage fluctuations in the electrical power E_{Supply}(t) supplied by the substation 530 and electrical power E_{meter}(t) received by the users 150, 160, with the VCC system 200. As seen in FIG. 7, before voltage control was applied (i.e., before t_0), the voltages 812, 814 (with an average voltage signal 810) of the electrical power E_{Supply}(t) supplied by the substation 530 generally fluctuated between, for example, about 123V and about 126V; and the voltage waveform 820 of the electrical power E_{Meter}(t) received by the users 150, 160, generally fluctuated between, for example, about 121V and 124V. After voltage control was applied, the voltage waveforms 812, 814 (810) generally fluctuated between, for example, about 120V and about 122V, and the voltage waveform 820 generally fluctuated between, for example, about 116V and about 121V. Accordingly, the VCC system 200 is able to operate the users 150, 160, in a lower band level.

Energy savings 807 (shown in FIG. 6) that result from operation of the VCC system 200, according to principles of the disclosure, may be measured and/or validated by measuring the voltage component V_{Supply}(t) and electrical power E_{Supply}(t) levels of electric power supplied by the substation 530 relative to the corresponding reference voltage set point V_{SP}(t) value. In the example shown in FIG. 7, the voltage V_{Supply}(t) and electrical energy E_{Supply}(t) levels may be measured at the transformer output (not shown) where the voltage control may be implemented. However, the measurement may be performed at any point where measurements could be made for the transmission or distribution systems.

FIG. 8 shows an example of data collected (including voltage and energy measurement) hourly by the DMS 480 (shown in FIG. 2), before time t_o (shown in FIG. 7), when voltage control is not carried out in the VCC system 200. As seen in FIG. 8, the collected data may include, for example, a date, a time (hour:minute:second), a power level (MWatt), a reactive power level (MVAr), a voltage (V), an apparent power level (MVA), a power factor (PF), loss factor, and loss FTR, of the electrical power E_{Supply}(t) output by the substation 530.

US 8,437,883 B2

23   24

FIG. 9 shows an example of data collected (including volt-age and energy measurement) hourly by the DMS **480** (shown in FIG. **2**), after time t_0 (shown in FIG. **7**), when voltage control is carried out in the VCC system **200**. As seen in FIG. **9**, the collected data may include, for example, a date, a time (hour:minute:second), a power level (MWatt), a reactive power level (MVAr), a voltage (V), an apparent power level (MVA), a power factor (PF), load financial transmission rights (FTR), and loss FTR, of the electrical power $E_{Supplied}(t)$ output by the substation **530** with voltage control carried out by the VCC system **200**.

Comparing the data in FIG. **8** to data of FIG. **9**, the voltage $V_{Supply}(t)$ and electrical power $E_{Supply}(t)$ measurements show the substantial impact of lowering voltage on the electric power usage by, for example, users **150**, **160**. In this regard, the hourly data at a transformer (not shown) in the substation **530** (shown in FIG. **2**) may be saved hourly. Voltage control and/or conservation may be carried according to the principles of the disclosure, and the energy use before (FIG. **8**) and after (FIG. **9**) implementation of the VCC system **200** may be compared at the two different voltage levels along the distribution circuit (for example, from or in the substation **530**). In the examples shown in FIGS. **8** and **9**, the before voltages may range from, for example, about 123V to about 125V, and the after voltages may range from, for example, about 120V to about 122V.

As shown in FIG. **7**, the VCC system **200** can monitor the twenty worst case voltages supplied by the distribution circuits and control the source bus voltage $V_{SP}(t)$ to maintain the operation in the lower band, as shown, for example, in FIG. **6**. The VCC system **200** can also reselect the smart meters **330** used for the 20 worse case voltages based on, for example, the information received from the EC system **400** "report-by-exception" monitoring of voltage. The VCC system **200** may select these new smart meters **330** from the total number of smart meters **330** connected to the substation **530**.

The voltage $V_{Supply}(t)$ and electrical power $E_{Supply}(t)$ data shown in FIGS. **8** and **9** may be arranged by hour and aver-aged over twenty-four hour periods, retaining the correct average of voltage to electrical power (MW) by calculating the voltage to electrical power (MW) value for each hour, adding for the twenty-four hours, calculating the weighted twenty-four hour voltage using the average hourly electrical power (MW) value and the total twenty-four hour electrical power (MW) to Voltage ratio for the day. This may produce one value for average electrical power (MW) per hour for a twenty-four hour period and a weighted voltage associated with this average electrical power usage.

FIG. **10** shows an example of calculation data for hours 1-5 and the average for the full twenty-four hours in the example of FIGS. **7-9**.

FIG. **11** shows an example where data may be collected for weather variables for the days before and after voltage control and/or conservation by the VCC system **200** according to the disclosure. In particular, FIG. **11** shows the data collected from the National Weather Service for, for example, Rich-mond International Airport, the nearest weather station loca-tion to the TRABUE SUBSTATION (shown in FIG. **3**). The data shown is for the same period as the example of FIG. **7**. The data shown in FIG. **11** may be used to eliminate as much of the changes in power, other than those caused by voltage, to provide as accurate a measurement as possible.

FIG. **12** shows an example of an application of the paired test analysis process, according to principles of the disclo-sure. As seen, kW usage per customer per day in the time period from May to January when, for example, the VCC is in the OFF mode, is compared to kW usage per customer per day

in the time period from January to November when, for example, the VCC is the ON mode. The Trabue Load growth demonstrates the process of pairing the test days from state **1** to sate **2**. Days from the pair **1** are picked from the May through January time period with voltage conservation turned OFF and matched with the days from the pair **2** period from, for example, January through November. The match may be based on the closest weather, season, day type, and relative humidity levels to remove as many other variables as pos-sible, except for the change in voltage. Because the data is collected over a long period of time, where economic and growth can also impact the comparison of the characteristics of growth or economic decline are removed by using the kW-per-customer data to remove effects in customer energy usage increases and decreases and a monthly linear regres-sion model to remove the growth or economic decline corre-lated to the month with the weather variables removed.

FIG. **13** shows an example of a scatterplot of a total power per twenty-four hours versus heating degree day. In this regard, the voltage and electrical power (MW) per hour may be recorded, and average voltage and electrical power (MW) per hour determined for a twenty-four hour period. The scat-terplot may be used to predict the power requirements for the next day using the closest power level day from the historical data stored in DB **470** (shown in FIG. **2**). The calculation may use as inputs the change in the variables from the nearest load day to the day being calculated and the output may be the new load level. Using these inputs and a standard linear regression calculation a model may be built for the historical data. The regression calculation may include, for example, the follow-ing expression [2]:

$$E_{Total/Customer} = -4.54 - 0.260 D_{Season} - 0.213 D_{Type} + 0.0579H + 0.0691 V_{Avg} + 0.00524 D_{Month} \qquad [2]$$

where: E_{Total} is a total power for a twenty-four hour period per customer for a particular day; D_{Type} is a day type (such as, for example, a weekend, a weekday, or a holiday) of the particu-lar day; D_{Season} is one of four seasons corresponding to the particular day in the calendar year; D_{Month} is the particular day in the month; H is a Heating Degree Day level for the particular day; and V is the V_{Avg} average voltage supplied per customer for the particular day.

The data shown in the example of FIG. **13** includes historic data for a 115 day period, before the VCC system **200** is implemented according to principles of the disclosure. The example shown in FIG. **12** may correspond to a winter season for TRABUE SUBSTATION loads. As seen in FIG. **13**, the model may be used represent the change in power level from one day to the next that is not related to the weather, growth, and economic variables in the linear regression expression [2].

The historical data may be adjusted to match the heating degree day level for the measurements taken after the voltage control and/or conservation is carried out by the VCC system **200**. For example, referring to FIG. **11**, a heating degree day of 19 may be read for a particular day, Feb. 1, 2009. The historical data may be searched in the DB **470** for all days with heating degree levels of 19. For example, two days in December may be found with the same heating degree day levels—for example, December 1 and 17. The linear regres-sion model expression [2] for the historical data may be used to adjust the variables for December 1 and 17 to the same values as the data taken on Feb. 1, 2009. This may provide as close a match between the historical (operating at the higher voltage level) and Feb. 1, 2009 (operating at the lower voltage level). The calculation of (change in MW)/(change in Volt-

US 8,437,883 B2

<table>
<tr><td>25</td><td>26</td></tr>
</table>

age) may be made from the high voltage to the low voltage operation. This may become one data point for the statistical analysis.

This process may be repeated for all measurements taken after the voltage conservation is turned on and compared to all similar days in the historical data taken for the matching season and other weather conditions. This may produce, for example, one-hundred-fifteen data points from, for example, 115 days of operation matched with all of the historical matching data. The resulting statistical analysis of this data is shown in FIGS. **13-14**.

The normality of the data may be validated using the Anderson-Darling Normality test. In the case of the example of FIGS. **13** and **14**, the P-Value may be 0.098, which may be well above the required value of 0.01, thereby demonstrating that the data may be normal with an approximately 99% confidence level, as shown in FIG. **14**. This allows the application of a one sample T test to demonstrate the average of the mean value of the change in electrical power (MW) to change in voltage. The test may be performed to evaluate the statistical significance of the average value being above, for example, about 1.0. As shown in FIG. **14** the test may demonstrate an approximately 99% confidence level that the savings in power to reduction in voltage may be above about 1.0% per 1% of voltage change. Using this type of statistical method continuous tracking of the energy saving improvement can be accomplished and recorded in kW/customer saved per day or aggregated to total kW saved for the customers connected to the substation **530**.

FIG. **15** shows an alternative example of a scatterplot of a total power per twenty-four hours versus heating degree day. In this regard, the voltage and electrical power (MW) per hour may be recorded, and average voltage and electrical power (MW) per hour determined for a twenty-four hour period. The scatterplot may be used to predict the power requirements for the next day using the closest power level day from the historical data stored in DB **470** (shown in FIG. 2). The calculation may use as inputs the change in the variables from the nearest load day to the day being calculated and the output may be the new load level. Using these inputs and a standard linear regression calculation a model may be built for the historical data. The regression calculation may include, for example, the following expression [3]:

$$E_{Total}=(-801+0.069Y+0.0722D_{Type}+0.094D_{Year}+$$
$$0.0138D_{Month}+0.126T_{max}+0.131T_{min}+9.84T_{avg}+$$
$$10.1H-10.3C+0.251P_{std})-(0.102T_{max-d}-$$
$$0.101T_{min-d}+0.892T_{avg-d}+0.693H_d-0.452C_d-$$
$$0.025P_R+0.967E_{TotalPrevious})$$

where: E_{Total} is a total power for a twenty-four hour period for a particular day; Y is a calendar year of the particular day; D_{Type} is a day type (such as, for example, a weekend, a weekday, or a holiday) of the particular day; D_{Year} is the particular day in the calendar year; D_{Month} is the particular day in the month; T_{max} is a maximum temperature for the particular day; T_{min} is minimum temperature for the particular day; T_{avg} is the average temperature for the particular day; H is a Heating Degree Day level for the particular day; C is a Cooling Degree Day level; P is a barometric pressure for the particular day; T_{max-d} is a maximum temperature for a closest comparison day to the particular day; T_{min-d} is minimum temperature for the closest comparison day to the particular day; T_{avg-d} is the average temperature for the closest comparison day to the particular day; H_d is a Heating Degree Day level for the closest comparison day to the particular day; C_d is a Cooling Degree Day level for the closest comparison day to the particular day; P_R is a Barometric pressure for the closest comparison day to the particular day; and $E_{TotalPrevious}$ is the total average hourly usage in MW on the closest comparison day to the particular day. The data shown in the example of FIG. **15** includes historic data for a fifty day period, before the VCC system **200** is implemented according to principles of the disclosure. The example shown in FIG. **15** may correspond to a winter season for TRABUE SUBSTATION loads. As seen in FIG. **15**, the model may represent 99.7% of the change in power level from one day to the next using the variables in the linear regression expression [3].

The historical data may be adjusted to match the heating degree day level for the measurements taken after the voltage control and/or conservation is carried out by the VCC system **200**. For example, referring to FIG. **11**, a heating degree day of 19 may be read for a particular day, Feb. 1, 2009. The historical data may be searched in the DB **470** for all days with heating degree levels of 19. For example, two days in December may be found with the same heating degree day levels—for example, December 1 and 17. The linear regression model expression [3] for the historical data may be used to adjust the variables for December 1 and 17 to the same values as the data taken on Feb. 1, 2009. This may provide as close a match between the historical (operating at the higher voltage level) and Feb. 1, 2009 (operating at the lower voltage level). The calculation of (change in MW)/(change in Voltage) may be made from the high voltage to the low voltage operation. This may become one data point for the statistical analysis.

This process may be repeated for all measurements taken after the voltage conservation is turned on and compared to all similar days in the historical data taken for the matching season and other weather conditions. This may produce, for example, seventy-one data points from, for example, thirty days of operation matched with all of the historical matching data. The resulting statistical analysis of this data is shown in FIG. **17**.

The normality of the data may be validated using the Anderson-Darling Normality test. In the case of the example of FIGS. **6** and **7**, the P-Value may be 0.305, which may be well above the required value of 0.02, thereby demonstrating that the data may be normal with an approximately 98% confidence level, as shown in FIG. **17**. This allows the application of a one sample T test to demonstrate the average of the mean value of the change in electrical power (MW) to change in voltage. The test may be performed to evaluate the statistical significance of the average value being above about 0.8. As shown in FIG. **17** the test may demonstrate an approximately 98% confidence level that the savings in power to reduction in voltage may be above about 0.8% per 1% of voltage change.

While the disclosure has been described in terms of exemplary embodiments, those skilled in the art will recognize that the disclosure can be practiced with modifications in the spirit and scope of the appended claims. These examples are merely illustrative and are not meant to be an exhaustive list of all possible designs, embodiments, applications or modifications of the disclosure.

What is claimed:

1. A voltage control and energy conservation system for an electric power transmission and distribution grid configured to supply electric power to a plurality of user locations, the system comprising:

   a substation including a supply point configured to supply electrical power to a plurality of user locations;

   a plurality of sensors, wherein each sensor is located at a respective one of a plurality of distribution locations on the distribution grid at or between the supply point and at least one of the plurality of user locations, and wherein

US 8,437,883 B2

27

each sensor is configured to sense a voltage of the supplied electric power at the respective distribution location and to generate measurement data based on the sensed voltage;

a voltage controller configured to receive measurement data from each sensor of a subset of the plurality of sensors, wherein the subset includes more than one and substantially fewer than all of the plurality of sensors, and to generate an energy delivery parameter based on a comparison of the measurement data received from the subset to a controller target voltage band;

a voltage adjusting device configured to adjust a voltage of the electric power supplied at the supply point based on the energy delivery parameter;

wherein at least one other sensor of the plurality of sensors that is not included in the subset is further configured to send a respective reporting signal to the voltage controller when the voltage sensed by the sensor is determined to be outside of a respective sensor target voltage band; and

wherein the voltage controller is configured to, in response to receiving the respective reporting signal, de-select a sensor from the subset and add to the subset the sensor that sent the respective reporting signal.

2. The system of claim 1, wherein the voltage adjusting device comprises:

a load tap change transformer that adjusts the voltage of the electric power supplied at the supply point based on a load tap change coefficient; or

a voltage regulator that adjusts the voltage of the electric power supplied at the supply point based on the energy delivery parameter.

3. The system of claim 1, wherein the voltage controller is further configured to determine an average voltage by averaging the measurement data received from the subset, and generate the energy delivery parameter based on the determined average voltage.

4. The system of claim 1, wherein the voltage controller is configured to:

store historical component data that includes at least one of aggregated energy component data at a substation level, voltage component data at a substation level, and weather data;

determine energy usage at each of the plurality of sensors;

compare the historical component data to the determined energy usage; and

determine energy savings attributable to the system based on the results of the comparison of the historical component data to the determined energy usage.

5. A method for controlling electrical power supplied to a plurality of distribution locations located at or between a supply point and at least one user location, each of the plurality of distribution locations including at least one sensor configured to sense a voltage of the supplied electric power at the respective distribution location and generate measurement data based on the sensed voltage, the method comprising:

receiving measurement data from a subset of the plurality of sensors, wherein the subset includes more than one but substantially fewer than all of the plurality of sensors;

adjusting a voltage at the supply point based on a comparison of the measurement data received from the subset to at least one controller target voltage band;

28

receiving a reporting signal indicating that a voltage that is sensed by another sensor that is not part of the subset is outside of a respective sensor target component band; and

in response to receiving the reporting signal, de-selecting a sensor from the subset and adding the other sensor to the subset.

6. The method of claim 5, wherein the act of adjusting a voltage at the supply point further comprises determining an average voltage by averaging the data received from the subset and generating the energy delivery parameter based on the determined average voltage.

7. The system of claim 1, wherein each sensor of the subset is located at a respective one of the plurality of user locations.

8. The system of claim 1, wherein at least one of the plurality of sensors is located on the distribution grid between the supply point and at least one of the user locations.

9. The system of claim 1, wherein the supply point is at a transformer at the substation.

10. The system of claim 1, wherein the plurality of sensors comprises a plurality of smart meters.

11. The system of claim 1, wherein the at least one sensor target voltage band comprises a plurality of sensor target voltage bands, each of the plurality of sensor target voltage bands corresponding to a respective sensor.

12. The system of claim 1, wherein the subset includes about twenty sensors on the distribution grid.

13. The system of claim 1, wherein the subset includes about ten sensors on a distribution circuit of the distribution grid.

14. The system of claim 13, wherein the distribution grid comprises two distribution circuits providing electric power to about 6400 user locations.

15. A controller for an energy conservation system for an electric power transmission and distribution grid configured to supply electric power from a supply point to a plurality of user locations, the controller comprising:

at least one processor configured to:

receive measurement data that is based on a measured component of electric power from each sensor of a subset of a plurality of sensors, wherein the plurality of sensors are located at respective distribution locations on the distribution grid at or between the supply point and at least one of the plurality of user locations, and wherein the subset includes more than one and substantially fewer than all of the plurality of sensors;

generate an energy delivery parameter based on a comparison of a controller target band to the measurement data received from the sensors in the subset; and

provide the energy delivery parameter to an adjusting device configured to adjust the electric power supplied at the supply point based on the energy delivery parameter; and

wherein the controller is configured to add to the subset at least one other sensor of the plurality of sensors in response to receiving a signal indicating that the measured component of electric power sensed by the at least one other sensor is outside of a sensor target component band.

16. The controller of claim 15, wherein the controller is further configured to de-select at least one of the sensors in the subset when adding the at least one other sensor to the subset.

17. The controller of claim 16, wherein the controller is configured to maintain a set number of sensors in the subset.

18. The controller of claim 17, wherein the set number of sensors is approximately twenty.

US 8,437,883 B2

29

30

19. The controller of claim **15**, wherein the measured component of electric power comprises at least one of: a voltage; a current; and a phase.

20. The controller of claim **15**, wherein the plurality of sensors comprises a plurality of smart meters.

CASE MANAGEMENT TRACK DESIGNATION FORM

|		
DOMINION RESOURCES, INC. and	:	CIVIL ACTION
VIRGINIA ELECTRIC AND POWER COMPANY	:	
v.	:	
	:	
ALSTOM GRID, INC.	:	NO.

In accordance with the Civil Justice Expense and Delay Reduction Plan of this court, counsel for plaintiff shall complete a Case Management Track Designation Form in all civil cases at the time of filing the complaint and serve a copy on all defendants. (See § 1:03 of the plan set forth on the reverse side of this form.) In the event that a defendant does not agree with the plaintiff regarding said designation, that defendant shall, with its first appearance, submit to the clerk of court and serve on the plaintiff and all other parties, a Case Management Track Designation Form specifying the track to which that defendant believes the case should be assigned.

SELECT ONE OF THE FOLLOWING CASE MANAGEMENT TRACKS:

(a) Habeas Corpus – Cases brought under 28 U.S.C. § 2241 through § 2255.   ( )

(b) Social Security – Cases requesting review of a decision of the Secretary of Health
    and Human Services denying plaintiff Social Security Benefits.   ( )

(c) Arbitration – Cases required to be designated for arbitration under Local Civil Rule 53.2.   ( )

(d) Asbestos – Cases involving claims for personal injury or property damage from
    exposure to asbestos.   ( )

(e) Special Management – Cases that do not fall into tracks (a) through (d) that are
    commonly referred to as complex and that need special or intense management by
    the court. (See reverse side of this form for a detailed explanation of special
    management cases.)   ( )

(f) Standard Management – Cases that do not fall into any one of the other tracks.   (X)
